| READING THE STEM — WHAT EACH INSTRUCTION<br>REQUIRES                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <div>HOW THE MARKS DIVIDE</div> <p>A question ending “<b>explain your answer</b>” carries the decision for one mark and a separate reason for each remaining mark. A <b>4</b>-mark question therefore needs the answer plus <b>3</b> distinct reasons, written as separate sentences.</p> |
| <div>COMMAND WORDS</div> <p>“State” and “identify” require the name only. “Explain” requires what happens <b>and</b> why it follows. “Show your working” means the arithmetic line itself carries a mark.</p>                                                                             |
| <p><b>Precision:</b> thermodynamics answers are given to <b>2 decimal places</b>. Elsewhere match the precision of the data supplied, and state the <b>unit</b> every time — several worksheets award a mark for it alone.</p>                                                            |

WORKED — GAS LAW IN BASE UNITS

Pressure from  $PV = nRT$

1.00 mol of nitrogen occupies 11.2 dm<sup>3</sup> at 0 °C. Calculate the pressure in kPa.

- Convert temperature:  $T = 0 + 273 = \mathbf{273 \text{ K}}$
- Convert volume: 11.2 dm<sup>3</sup>  $\div$  1000 = **0.0112 m<sup>3</sup>**
- Rearrange:  $P = nRT \div V$
- Substitute:  $P = (1.00)(8.314)(273) \div 0.0112$
- $P = 202 \text{ 654 Pa} \rightarrow 1000$

P = **202.65 kPa**

WORKED — MOLAR MASS, MOLES AND PARTICLES

Three quantities from one sample

A sample contains 76.00 g of fluorine gas, F<sub>2</sub>. Calculate its molar mass, the number of moles present, and the number of molecules.

- Molar mass: F<sub>2</sub> has two fluorine atoms, so  $M = 2 \times 19.00 = \mathbf{38.00 \text{ g/mol}}$
- Moles:  $n = m \div M = 76.00 \div 38.00 = \mathbf{2.00 \text{ mol}}$
- Molecules:  $N = n \times 6.02 \times 10^{23}$
- $N = 2.00 \times 6.02 \times 10^{23}$
- The question asks for molecules, not atoms. Each F<sub>2</sub> holds two atoms, so the atom count would be twice this

M = 38.00 g/mol  
n = 2.00 mol  
N = **1.20  $\times 10^{24}$  molecules**

WORKED — IDENTIFYING A GAS FROM ITS DENSITY DATA

Which gas is it

0.71 g of an unknown gas occupies 250 cm<sup>3</sup> at 101 kPa and 30.7 °C. Identify the gas.

- Convert temperature to base units:  $V = 250 \text{ cm}^3 = \mathbf{0.00025 \text{ m}^3}$ ,  $P = 101 \text{ kPa} = \mathbf{101 \text{ 000 Pa}}$ ,  $T = 30.7 + 273 = \mathbf{303.7 \text{ K}}$

- Find the moles:  $n = PV \div RT$
- $n = (101 \text{ 000} \times 0.00025) \div (8.314 \times 303.7) = 25.25 \div 2524.9$
- $n = \mathbf{0.0100 \text{ mol}}$
- Molar mass:  $M = \text{mass} \div n = 0.71 \div 0.0100 = \mathbf{71 \text{ g/mol}}$
- Match it: Cl<sub>2</sub> is  $2 \times 35.45 = 70.90 \text{ g/mol}$

The gas is **chlorine, Cl<sub>2</sub>**

| RELATIVE ATOMIC MASSES IN COMMON USE |                |                     |        |

WORKED — PERCENTAGE CHANGE IN VOLUME

Volume change when pressure and temperature both alter

1.5 mol of gas is at 101.3 kPa and 298 K. It is taken to 54.0 kPa and 258 K. Calculate the percentage increase in volume.

- There is **no combined gas law here**, so either apply  $PV = nRT$  twice, or take the ratio directly
- By the ratio:  $V_2/V_1 = (P_1 \div P_2) \times (T_2 \div T_1)$
- Pressure factor: 101.3  $\div$  54.0 = 1.876
- Temperature factor: 258  $\div$  298 = 0.866
- $V_2/V_1 = 1.876 \times 0.866 = \mathbf{1.624}$
- Percentage increase =  $(1.624 - 1) \times 100$

Volume increases by **62.4%**

WORKED — BALANCING, THEN READING THE MOLE RATIO

From an unbalanced equation to an amount

Balance C<sub>5</sub>H<sub>12</sub> + O<sub>2</sub>  $\rightarrow$  CO<sub>2</sub> + H<sub>2</sub>O, then state how many moles of oxygen react with 0.30 mol of C<sub>5</sub>H<sub>12</sub>.

- Balance carbon first: 5 C on the left, so **5CO<sub>2</sub>**
- Balance hydrogen next: 12 H on the left, so **6H<sub>2</sub>O**
- Count the oxygen now fixed on the right: 5(2) + 6(1) = **16 atoms**
- Oxygen arrives as O<sub>2</sub>, so 16  $\div$  2 = **8O<sub>2</sub>**
- Balanced: C<sub>5</sub>H<sub>12</sub> + **8O<sub>2</sub>**  $\rightarrow$  **5CO<sub>2</sub>** + **6H<sub>2</sub>O**
- Ratio C<sub>5</sub>H<sub>12</sub> : O<sub>2</sub> = 1 : 8, so 0.30 mol needs 0.30  $\times$  8

**2.40 mol** of oxygen. Balance **before** reading any ratio

WORKED — TITRATION WITH A 2 : 1 RATIO

**Concentration of NaOH by titration against H<sub>2</sub>SO<sub>4</sub>**

10.00 mL of NaOH is titrated against 0.0252 mol/L H<sub>2</sub>SO<sub>4</sub>. Titrates: 15.10, 15.00, 14.90, 15.00 mL, all recorded as accurate.  
2 NaOH + H<sub>2</sub>SO<sub>4</sub> → Na<sub>2</sub>SO<sub>4</sub> + 2 H<sub>2</sub>O

- Average the accurate titres: (15.10 + 15.00 + 14.90 + 15.00) ÷ 4 = **15.00 mL**
- Moles of the known solution: n(H<sub>2</sub>SO<sub>4</sub>) = 0.0252 × 0.01500 L = **3.78 × 10<sup>-4</sup> mol**
- Mole ratio from the equation is NaOH : H<sub>2</sub>SO<sub>4</sub> = **2 : 1**, so **multiply** by 2
- n(NaOH) = 2 × 3.78 × 10<sup>-4</sup> = 7.56 × 10<sup>-4</sup> mol
- Divide by the NaOH volume: 7.56 × 10<sup>-4</sup> ÷ 0.01000 L

[NaOH] = **0.0756 mol/L**

WORKED — LIMITING REAGENT AND PRODUCT MASS

**Mass of copper deposited**

4.20 g of zinc is added to 200 mL of 0.250 mol/L copper(II) sulfate. Zn(s) + CuSO<sub>4</sub>(aq) → ZnSO<sub>4</sub>(aq) + Cu(s). Calculate the mass of copper formed.

- Moles of zinc: n = 4.20 ÷ 65.38 = **0.0642 mol**

- Moles of copper(II) sulfate: n = M × V = 0.250 × 0.200 L = **0.0500 mol**
- The ratio is **1 : 1**, so each would give that many moles of Cu
- CuSO<sub>4</sub> gives the smaller amount, so **CuSO<sub>4</sub> is limiting** — even though there is less zinc by mass
- n(Cu) = 0.0500 mol, and M(Cu) = 63.55 g/mol
- m = 0.0500 × 63.55

Mass of copper = **3.18 g**

LIMITING REAGENT

|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| two amounts given, or “which is limiting” | 1. for <b>each</b> reactant, find how much product it alone would give<br>2. the smaller product amount identifies the limiting reagent<br>3. the other is in excess | 4 mol CO (1:1) → 4 mol H <sub>2</sub> (2:1) → 3 mol H <sub>2</sub> gives less → H <sub>2</sub> limiting |
| “how much remains”                        | excess = starting amount – amount consumed                                                                                                                           | 0.60 mol H <sub>2</sub> , 0.40 consumed → 0.20 mol left                                                 |
| common error                              | <b>the smaller starting amount is not necessarily limiting</b>                                                                                                       | Zn 0.0642 mol vs CuSO <sub>4</sub> 0.0500 mol at 1:1 → CuSO <sub>4</sub> limits                         |
| one amount given as a solution            | convert first: n = M × V                                                                                                                                             | 0.250 M × 0.200 L = 0.0500 mol                                                                          |

TITRATION TECHNIQUE, AND STANDARDISATION

**Why NaOH is standardised:** it cannot be weighed accurately because it is **hygroscopic** and absorbs CO<sub>2</sub> from the air, so its concentration must be found against an acid of known concentration.

**Technique:** read the meniscus at the **bottom**; no air bubble in the burette tip; add dropwise near the endpoint; phenolphthalein as indicator.

**MODEL ANSWER — STANDARDISATION**  
The concentration of sodium hydroxide cannot be determined by weighing because it is **hygroscopic** and absorbs **carbon dioxide** from the air, so its mass is not reliable. It is therefore standardised against **a solution of known concentration**.

**Outside the syllabus:** STP and 22.4 L/mol; Gay-Lussac; the combined gas law; percent composition; empirical and molecular formula; ppm and % w/w.

WORKED — DILUTION FROM A STOCK SOLUTION

**Concentration after dilution**

25 mL of 6.0 mol/L glucose is pipetted into a 250 mL volumetric flask and made up to the mark. Calculate the moles transferred and the final concentration.

- Moles pipetted: n = M × V = 6.0 × 0.025 L = **0.15 mol**

- Dilution adds solvent, not solute**, so this 0.15 mol is unchanged by the dilution
- Apply M<sub>1</sub>V<sub>1</sub> = M<sub>2</sub>V<sub>2</sub>. Here V<sub>1</sub> = 25 mL and **V<sub>2</sub> = 250 mL, the flask capacity** — not the 225 mL of water added
- M<sub>2</sub> = (6.0 × 25) ÷ 250
- Check against the moles: 0.15 mol ÷ 0.250 L = 0.60 mol/L, which agrees

n = 0.15 mol transferred  
final concentration = **0.60 mol/L**

MODEL WORDING — SOLUTIONS AND TECHNIQUE

**STATING A TITRATION RESULT**  
The concentration is **0.0756 mol/L**. From the balanced equation the ratio of **NaOH** to **H<sub>2</sub>SO<sub>4</sub>** is **2 : 1**, so the moles of **NaOH** are **twice** those of the acid.

**WHY A ROUGH TITRE IS DISCARDED**  
The rough titre is excluded because it is only an approximate value used to locate the endpoint. Averaging the **accurate** titres gives **15.00 mL**.

| THE FOUR CONCENTRATION UNITS, SIDE BY SIDE |                                                                                        |                                                |
|--------------------------------------------|----------------------------------------------------------------------------------------|------------------------------------------------|
| UNIT                                       | DIVIDED BY                                                                             | WORKED                                         |
| <b>percent by mass, %</b>                  | mass of the whole <b>solution</b>                                                      | 0.30 g in 0.30 + 0.50 g → 0.30/0.80 = 37.50%   |
| <b>mass concentration, g/L</b>             | volume of solution in <b>litres</b>                                                    | 0.35 g in 1 L → 0.35 g/L                       |
| <b>molality, mol/kg</b>                    | <b>mass of the SOLVENT in kg</b>                                                       | 0.30 mol in 0.50 kg water → 0.60 mol/kg        |
| <b>molarity, mol/L</b>                     | volume of <b>solution</b> in litres                                                    | 0.30 mol in 0.60 L → 0.50 mol/L                |
| <b>the one difference</b>                  | <b>molality divides by the solvent; every other unit divides by the whole solution</b> | the same 0.30 mol gives four different numbers |

**WORKED — CONCENTRATION FROM A TITRATION WITH PH DATA**

**Using pH to obtain the titrant concentration first**

A burette holds hydrochloric acid of pH 1.50. It is titrated against 25.00 mL of NaOH. Titrates: 8.70, 8.80, 8.60, 8.90 mL. HCl + NaOH → NaCl + H<sub>2</sub>O. Find [NaOH].

- Convert the pH: [H<sup>+</sup>] = 10<sup>-1.50</sup> = **0.0316 mol/L**
- HCl is monoprotic, so [HCl] = [H<sup>+</sup>] = **0.0316 mol/L**
- Average the titres: (8.70 + 8.80 + 8.60 + 8.90) ÷ 4 = **8.75 mL**
- Moles of acid: n = 0.0316 × 0.00875 L = **2.77 × 10<sup>-4</sup> mol**
- The ratio is **1 : 1**, so n(NaOH) is the same
- Divide by the NaOH volume: 2.77 × 10<sup>-4</sup> ÷ 0.02500 L

[NaOH] = **0.0111 mol/L**

| "FIND THE PH OF..." — IDENTIFYING THE CASE                                                            |                                    |                                                                                           |

| ACIDS — SCOPE NOTES AND MODEL WORDING                                                                                                                                                                                                                                                                                                               |  |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <b>MODEL ANSWER — LE CHATELIER</b><br>The equilibrium shifts to the <b>left</b> , because increasing the <b>temperature</b> favours the <b>endothermic</b> direction, which absorbs the added heat. The amount of <b>CH<sub>4</sub></b> therefore <b>decreases</b> .                                                                                |  |
| <b>MODEL ANSWER — BUFFER IDENTIFICATION</b><br>This mixture <b>is</b> a buffer, because it contains a weak acid, <b>HNO<sub>2</sub></b> , together with its conjugate base, <b>NO<sub>2</sub><sup>-</sup></b> , supplied by the salt. Added acid is removed by the conjugate base and added alkali by the weak acid, so the pH changes very little. |  |
| <b>Outside the syllabus:</b> ICE tables, K <sub>p</sub> and partial pressures, K <sub>w</sub> as a symbol, K <sub>a</sub> × K <sub>b</sub> = K <sub>w</sub> , the "x is small" approximation, pH of a weak base from K <sub>b</sub> alone, pH of a salt solution, and omitting pure solids from K <sub>c</sub> .                                    |  |
| <b>Two printing errors in the notes.</b> One equilibrium equation reads <b>PCl<sub>5</sub> ⇌ PCl<sub>5</sub> + Cl<sub>2</sub></b> , which is impossible; the left side should be PCl <sub>3</sub> . Another gives <b>SO<sub>2</sub> + O<sub>2</sub> ⇌ 2SO<sub>3</sub></b> unbalanced; it should read 2SO <sub>2</sub> .                             |  |
| <b>pK<sub>a</sub> of ethanoic acid</b> appears once as 4.76 and elsewhere as <b>4.74</b> . Use <b>4.74</b> .                                                                                                                                                                                                                                        |  |

| WORKED — A WEAK ACID AND A STRONG ACID AT THE SAME PH                                                                                                                                                               |  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <b>pH, K<sub>a</sub>, and what pH cannot tell you</b>                                                                                                                                                               |  |
| A 0.010 mol/L solution of the weak acid HY is 5% dissociated. Calculate its pH and K <sub>a</sub> . A 0.0005 mol/L solution of the strong acid HX is also measured. Comment on what pH reveals about acid strength. |  |
| <b>1.</b> Dissociated fraction: [H <sup>+</sup> ] = [Y <sup>-</sup> ] = 5% × 0.010 = <b>5.0 × 10<sup>-4</sup> mol/L</b>                                                                                             |  |
| <b>2.</b> Undissociated acid remaining: [HY] = 95% × 0.010 = <b>0.0095 mol/L</b>                                                                                                                                    |  |
| <b>3.</b> pH = -log(5.0 × 10 <sup>-4</sup> ) = <b>3.30</b>                                                                                                                                                          |  |
| <b>4.</b> K <sub>a</sub> = [H <sup>+</sup> ][Y <sup>-</sup> ] ÷ [HY] = (5.0 × 10 <sup>-4</sup> ) <sup>2</sup> ÷ 0.0095 = <b>2.6 × 10<sup>-5</sup></b>                                                               |  |
| <b>5.</b> For the strong acid, dissociation is complete: [H <sup>+</sup> ] = 0.0005, so pH = -log(0.0005) = <b>3.30</b>                                                                                             |  |
| <b>6. Both solutions have pH 3.30</b> , yet one acid is weak and the other strong                                                                                                                                   |  |
| <b>pH depends on concentration as well as strength, so it cannot distinguish a weak acid from a strong one. Only K<sub>a</sub> can</b>                                                                              |  |

route 1

route 2

ELEMENTS

Both routes begin and end together, so both cost the same. Going against an **arrow flips that  $\Delta H$** ; **scaling scales it**.

### WORKED — HESS'S LAW WITH TWO REVERSALS

**Enthalpy of formation of ammonium chloride**

Calculate  $\Delta_{\text{rxn}}H$  for  $\text{NH}_3(\text{g}) + \text{HCl}(\text{g}) \rightarrow \text{NH}_4\text{Cl}(\text{s})$ .

Given: (1)  $\frac{1}{2}\text{N}_2 + \frac{1}{2}\text{H}_2 \rightarrow \text{NH}_3$ ,  $\Delta H = -46.1 \text{ kJ}$  (2)  $\frac{1}{2}\text{H}_2 + \frac{1}{2}\text{Cl}_2 \rightarrow \text{HCl}$ ,  $\Delta H = -92.3 \text{ kJ}$  (3)  $\frac{1}{2}\text{N}_2 + 2\text{H}_2 + \frac{1}{2}\text{Cl}_2 \rightarrow \text{NH}_4\text{Cl}$ ,  $\Delta H = -314.4 \text{ kJ}$

- $\text{NH}_3$  must be a **reactant**, but is a product in (1). **Reverse (1)**  $\rightarrow \Delta H = +46.1$
- $\text{HCl}$  must be a **reactant**, but is a product in (2). **Reverse (2)**  $\rightarrow \Delta H = +92.3$
- $\text{NH}_4\text{Cl}$  is already a product in (3). **Keep (3)**  $\rightarrow \Delta H = -314.4$
- No coefficient is wrong, so nothing is scaled
- Add: the  $\frac{1}{2}\text{N}_2$ ,  $2\text{H}_2$  and  $\frac{1}{2}\text{Cl}_2$  appear on both sides and cancel, leaving  $\text{NH}_3 + \text{HCl} \rightarrow \text{NH}_4\text{Cl}$
- Sum the enthalpies:  $46.1 + 92.3 - 314.4$

$\Delta_{\text{rxn}}H = -176.00 \text{ kJ}$ , exothermic

### WORKED — SPONTANEITY AT TWO TEMPERATURES

**The Haber process**

For  $\text{N}_2(\text{g}) + 3\text{H}_2(\text{g}) \rightarrow 2\text{NH}_3(\text{g})$ ,  $\Delta H = -92.2 \text{ kJ/mol}$  and  $\Delta S = -0.199 \text{ kJ mol}^{-1}\text{K}^{-1}$ . Determine whether the reaction is spontaneous at 298 K and at 773 K.

- $\Delta S$  is already in **kJ**, so no conversion is needed
- At 298 K:  $\Delta G = -92.2 - (298)(-0.199)$
- Two negatives give a plus**:  $-92.2 + 59.30 = -32.90 \text{ kJ/mol}$ , spontaneous
- At 773 K:  $\Delta G = -92.2 - (773)(-0.199) = -92.2 + 153.83$
- $= +61.63 \text{ kJ/mol}$** , not spontaneous
- Crossover:  $T = \Delta H \div \Delta S = -92.2 \div -0.199 = \mathbf{463.3 \text{ K}}$ , which explains both results

Spontaneous at 298 K, not at 773 K. Both  $\Delta H$  and  $\Delta S$  negative  $\rightarrow$  spontaneous only **below** 463.3 K

| SPONTANEITY — THE FOUR CASES          |                                                                     |                                                                                      |

|                                       | $\Delta H$ NEGATIVE (EXOTHERMIC)                                    | $\Delta H$ POSITIVE (ENDOTHERMIC)                                                    |
| <b><math>\Delta S</math> positive</b> | <b>spontaneous at all temperatures</b>                              | spontaneous at high $T$ , once $T\Delta S$ is large enough                           |
| <b><math>\Delta S</math> negative</b> | spontaneous at <b>low</b> $T$ , while $T\Delta S$ is small          | <b>never spontaneous</b>                                                             |
| reason                                | only the <b><math>T\Delta S</math></b> term varies with temperature | where $\Delta H$ and $\Delta S$ agree in sign, temperature cannot change the verdict |

### ENERGY — UNITS, CONVENTIONS AND MODEL WORDING

#### MODEL ANSWER — SPONTANEITY

The reaction is **spontaneous** at **298 K**, because  $\Delta G = \Delta H - T\Delta S = \mathbf{-32.90 \text{ kJ/mol}}$ , which is **negative**. A negative free energy change indicates a spontaneous process.

#### MODEL ANSWER — ENTROPY CHANGE

Entropy **increases**, because the number of particles rises from **2 to 3**, and because **a gas** is produced where there was none. A gas has the greatest number of possible arrangements.

**Units**: tabulated data are in **kJ/mol**; calculated answers in **kJ**, unless an enthalpy **of formation** is asked for, which is per mole. Entropy tables are in **J**; divide by 1000 before combining with an enthalpy.

**Signs**:  $-\Delta H$  exothermic, heat released.  $+\Delta H$  endothermic, heat absorbed. Breaking bonds absorbs (+), forming bonds releases (-).

“**Gives out 81.67 kJ**” means  **$\Delta H = -81.67$** . The minus sign is not written in the question.

Thermodynamics answers are given to **2 decimal places**. **Calorimetry ( $q = mc\Delta T$ ) is outside the syllabus**.

### WORKED — ENTHALPY FROM BOND ENTHALPIES

**Combustion of propanone**

$\text{CH}_3\text{COCH}_3(\text{g}) + 4\text{O}_2(\text{g}) \rightarrow 3\text{CO}_2(\text{g}) + 3\text{H}_2\text{O}(\text{g})$ . Bond enthalpies in kJ/mol: C-H 412, C-C 348, C=O 805, O=O 496, O-H 463.

- Count the bonds broken. Propanone is  $\text{H}_3\text{C-CO-CH}_3$ : **6** C-H, **2** C-C, **1** C=O. Plus **4** O=O in the oxygen
- Breaking =  $6(412) + 2(348) + 805 + 4(496) = 2472 + 696 + 805 + 1984 = \mathbf{+5957 \text{ kJ}}$
- Count the bonds formed. **Each  $\text{CO}_2$  holds two C=O**, so 3  $\text{CO}_2$  gives **6** C=O. Each  $\text{H}_2\text{O}$  holds two O-H, so 3  $\text{H}_2\text{O}$  gives **6** O-H
- Forming =  $6(805) + 6(463) = 4830 + 2778 = \mathbf{-7608 \text{ kJ}}$
- $\Delta H = \text{breaking} + \text{forming} = 5957 + (-7608)$

$\Delta_{\text{rxn}}H = -1651.00 \text{ kJ}$ . A combustion returning a positive value has the two terms the wrong way round

| <b>IDENTIFYING AN AGENT</b><br>The oxidising agent is <b><math>MnO_4^-</math></b> , because the oxidation state of <b>manganese</b> falls from <b>+7</b> to <b>+2</b> . It gains electrons and is itself reduced, so it oxidises the other species.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| <b>ELECTRON DIRECTION</b><br>Electrons flow from <b>chromium</b> to <b>nickel</b> , because <b>chromium</b> is the anode, where oxidation releases electrons. They travel through the external circuit to the cathode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |
| <b>RATE EXPLANATION</b><br>The rate increases, because raising the <b>temperature</b> increases the proportion of molecules with energy greater than the activation energy, and also increases the frequency of collisions. This increases the number of <b>successful collisions</b> per second.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |
| <b>AGREE OR DISAGREE</b><br>Yes. The pump moves <b>two different</b> species in <b>opposite</b> directions, which is the definition of an antiporter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| <b>WORKED — ORDER OF REACTION FROM HALF-LIFE</b><br><b>Finding the order, then testing a mechanism</b><br>The concentration of G falls 0.40, 0.20, 0.10, 0.05, 0.025, 0.0125 mol/L at 0, 12, 24, 36, 48, 60 s. Determine the order with respect to G, and decide which mechanism is consistent: (I) slow step $G + H_2 \rightarrow GH + H$ , or (II) slow step $2G \rightarrow G_2$ . <ol style="list-style-type: none"> <li>Read the half-lives off the table. 0.40 → 0.20 takes <b>12 s</b></li> <li>0.20 → 0.10 takes <b>12 s</b>; 0.10 → 0.05 takes <b>12 s</b></li> <li>The half-life is <b>constant</b> and does not depend on the starting concentration</li> <li>A constant half-life is the signature of <b>first order</b></li> <li><b>In an elementary step only</b>, the order equals the coefficient. Mechanism I gives rate = <math>k[G][H_2]</math>, first order in G</li> <li>Mechanism II gives rate = <math>k[G]^2</math>, second order in G, which contradicts the data</li> </ol> <div>First order in G, and <b>mechanism I</b> is the consistent one</div>                                                                      |  |
| <b>WORKED — RATE LAW, AND THE EFFECT OF CHANGING A CONCENTRATION</b><br><b>Rate constant and its units</b><br>For a reaction, rate = $k[P][Q]^2$ . When $[P] = 0.100$ mol/L and $[Q] = 0.400$ mol/L the rate is $0.12 \text{ mol L}^{-1} \text{ s}^{-1}$ . State the orders, calculate k with its units, and give the effect of doubling each concentration. <ol style="list-style-type: none"> <li>Orders read straight off the exponents: <b>first</b> in P, <b>second</b> in Q, <b>third</b> overall</li> <li>Rearrange: <math>k = \text{rate} \div ([P][Q]^2)</math></li> <li><math>k = 0.12 \div (0.100 \times 0.400^2) = 0.12 \div 0.0160</math></li> <li>Units: k carries <math>M^{(1 - \text{overall order})} s^{-1}</math>, so for third order that is <b><math>M^{-2} s^{-1}</math></b></li> <li>Doubling <math>[P]</math>: first order, so the rate changes by <math>2^1 = \mathbf{\times 2}</math></li> <li>Doubling <math>[Q]</math>: second order, so <math>2^2 = \mathbf{\times 4}</math></li> </ol> <div><math>k = \mathbf{7.5 \text{ M}^{-2} \text{ s}^{-1}}</math><br/>doubling P doubles the rate, doubling Q quadruples it</div> |  |
| <b>WORKED — ARRHENIUS WITH A CATALYST</b><br><b>Rate constant at a second temperature</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |  |

| At 400 °C with $E_a = 30 \text{ kJ/mol}$ , $k = 3.7 \times 10^{-5} \text{ s}^{-1}$ . |-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <b>A chromium and nickel voltaic cell</b>                                                                                                                                                                                                                                                     |  |
| Two half-cells are joined by a salt bridge. Ni <sup>2+</sup> + 2e <sup>−</sup> → Ni, E° = −0.28 V. Cr <sup>3+</sup> + 3e <sup>−</sup> → Cr, E° = −0.74 V. Chromium is on the left. Give the electrode reactions, the overall equation, the cell potential and the direction of electron flow. |  |
| <b>1.</b> Compare the potentials: −0.28 is <b>more positive</b> than −0.74, so <b>Ni<sup>2+</sup> is reduced</b> and is the <b>cathode</b>                                                                                                                                                    |  |
| <b>2.</b> Chromium is therefore oxidised and is the <b>anode</b> . Reverse its equation and flip the sign: Cr → Cr <sup>3+</sup> + 3e <sup>−</sup> , E° <sub>ox</sub> = <b>+0.74 V</b>                                                                                                        |  |
| <b>3.</b> Balance the electrons: the Cr half × <b>2</b> and the Ni half × <b>3</b> gives 6 electrons each way                                                                                                                                                                                 |  |
| <b>4.</b> The <b>E° values are not scaled</b> . They stay at +0.74 and −0.28                                                                                                                                                                                                                  |  |
| <b>5.</b> E° <sub>cell</sub> = E° <sub>ox</sub> + E° <sub>red</sub> = 0.74 + (−0.28)                                                                                                                                                                                                          |  |
| <b>6.</b> Electrons leave the anode, which is the chromium on the <b>left</b> , and travel through the external circuit to the cathode on the right                                                                                                                                           |  |

|                                                                                                                                 |

| Establishing                   | the true concentration of a NaOH solution that cannot be found by weighing                                                                                                                                                                                                                                                                | NaOH is <b>hygroscopic</b> and absorbs CO <sub>2</sub> , so the mass weighed out is not the mass of NaOH present |
| Method                         | <ol style="list-style-type: none"><li>fill the burette with the <b>0.010 M HCl</b> of known concentration</li><li>pipette a fixed volume of the NaOH into a conical flask</li><li>add two drops of <b>phenolphthalein</b></li><li>titrate until the pink just disappears, swirling throughout</li><li>repeat until titres agree</li></ol> | the known solution goes in the burette because it is the one being measured out against the unknown              |
| Assumes                        | the HCl really is 0.010 M, the pipette delivers its stated volume, and the indicator changes at the equivalence point                                                                                                                                                                                                                     | a systematic error in any of these shifts every titre the same way, so repeats will not reveal it                |
| Common trips                   | <b>an air bubble under the tap</b> leaves during the run and adds to the titre reading the <b>top</b> of the meniscus including the <b>rough</b> titre in the average rinsing the conical flask with the NaOH                                                                                                                             | each of these biases the result in one direction, which is what makes them systematic rather than random         |
| Happy path                     | three titres within 0.10 mL of one another, a sharp colour change on one drop                                                                                                                                                                                                                                                             | average the accurate titres, then n = MV and the 1 : 1 ratio                                                     |
| Sad path                       | <b>titres drift upward run to run</b> → a bubble left the tip, or the burette leaks <b>colour fades back</b> → CO <sub>2</sub> absorbed, or the end point was overshot <b>titres scatter randomly</b> → inconsistent swirling or end-point judgement                                                                                      | a <b>drift</b> is systematic and must be fixed; scatter is random and is reduced by repeating                    |

**BURETTE**  
the solution of KNOWN concentration goes here  
read at the **BOTTOM** of the meniscus, to 0.05 mL

**TAP**  
no air bubble below it, or the titre reads high

**CONICAL FLASK**  
the UNKNOWN, pipetted, plus 2 drops of indicator

**Swirl constantly, and add dropwise near the end point.**  
Phenolphthalein is colourless in acid and pink in alkali.

| FINDING THE CONCENTRATION OF SULFURIC ACID |                                                                                                                                              |                                                                                                                       |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| STAGE                                      | DETAIL                                                                                                                                       | WHY IT IS DONE THIS WAY                                                                                               |
| Establishing                               | the molarity of an unknown H <sub>2</sub> SO <sub>4</sub> solution                                                                           | it follows the first experiment, and uses the NaOH that was standardised there                                        |
| Method                                     | as before, but the balanced equation is now<br><b>2 NaOH + H<sub>2</sub>SO<sub>4</sub> → Na<sub>2</sub>SO<sub>4</sub> + 2 H<sub>2</sub>O</b> | the apparatus does not change; only the arithmetic does                                                               |
| The one difference that matters            | <b>the ratio is 2 : 1, not 1 : 1</b>                                                                                                         | n(NaOH) = 2 × n(H <sub>2</sub> SO <sub>4</sub> ). The species with the larger coefficient takes the larger mole count |
| Common trips                               | carrying the 1 : 1 habit over from the first experiment using the nominal NaOH concentration instead of the <b>standardised</b> one          | the whole point of the first experiment was to replace the nominal value                                              |
| Happy path                                 | a result consistent with the acid label, concordant titres                                                                                   | quote the unit, and match the precision of the data                                                                   |
| Sad path                                   | <b>the answer is out by a factor of two</b> → the mole ratio was applied upside down or omitted                                              | a factor of exactly 2 is almost always the ratio, not the arithmetic                                                  |

| PREPARING A STANDARD SOLUTION, AND READING THE GLASSWARE |                                                                                                                                                                                       |                                                                                                        |
|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| POINT                                                    | DETAIL                                                                                                                                                                                | CONSEQUENCE IF IGNORED                                                                                 |
| choosing apparatus                                       | <b>volumetric</b> glassware for anything that must be precise: bulb pipette, volumetric flask, burette <b>ordinary</b> for everything else: beaker, conical flask, measuring cylinder | measuring a precise volume in a beaker discards the precision the calculation assumes                  |
| the transfer                                             | dissolve in a small volume first, transfer through a funnel, then <b>rinse three times</b> into the flask                                                                             | solute left in the beaker makes the solution <b>too dilute</b> , and the error is invisible afterwards |

**PREPARING A STANDARD SOLUTION, AND READING THE GLASSWARE**

| POINT      | DETAIL                                                     | CONSEQUENCE IF IGNORED                                       |
|------------|------------------------------------------------------------|--------------------------------------------------------------|
| topping up | dropper for the last drops, then stopper and invert to mix | overshooting the line cannot be corrected by removing liquid |
| reading    | bottom of the meniscus, at eye level                       | reading from above gives a consistently low volume           |

- dissolve the solid in a small volume, in a beaker
- transfer to the flask through a filter funnel
- rinse the beaker and transfer, three times
- top up to the line, dropper at the end
- stopper and invert to mix thoroughly

**Rinsing matters: solute left behind makes the solution too dilute.**

**CORRECT**  
bottom

**WRONG**  
top

**Read the BOTTOM of the meniscus, eye level.**

**SERIAL DILUTION**

| STAGE          | DETAIL                                                                                                  | NOTE                                                              |
|----------------|---------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| Establishing   | a solution far more dilute than one step could produce                                                  | used in chemical analysis, microbiology and pharmacology          |
| Method         | transfer one part into nine parts of solvent, and repeat                                                | each step is a factor of ten                                      |
| The arithmetic | dilution factors <b>multiply</b>                                                                        | 10 × 10 × 10 = 1000, in three manageable steps                    |
| Common trips   | adding solvent <b>to the mark</b> rather than making up <b>to the mark</b> failing to mix between steps | an unmixed step carries its error into every step after it        |
| Sad path       | <b>the final concentration is out by a power of ten</b>                                                 | one step was skipped, or a factor was added instead of multiplied |

**1.0 M   0.1 M   0.01 M   0.001 M**

Take 1 part into 9 parts of solvent, four times over. Dilution factors **MULTIPLY**: 10 × 10 × 10 × 10 = 10000.

One 1000-fold step in a single flask cannot be measured accurately, which is why the chain is used.

| <b>MODEL ANSWER, AN ERROR QUESTION</b> | <p>The result would be <b>too high</b>, because <b>the air bubble</b> leaves the burette tip during the titration and is recorded as though it were <b>titrant delivered</b>. This is a <b>systematic</b> error, so repeating the titration would not remove it.</p>                                                                                                                                                                                                                                                  |
| <b>MODEL ANSWER, WHY A STEP EXISTS</b> | <p>The two solutions must be <b>standardised</b> first because <b>sodium hydroxide</b> absorbs moisture and carbon dioxide from the air, so its concentration cannot be calculated from the <b>mass weighed out</b>.</p> <p><b>Systematic or random:</b> an error that shifts every result the <b>same way</b> is systematic, and repeating will not remove it. An error that scatters results is random, and averaging reduces it. Nearly every practical question turns on which of the two is being described.</p> |
